Abstract

This paper presents the Firefighter Optimization (FFO) algorithm as a new metaheuristic for optimization problems that stems inspiration from the collaborative strategies often deployed by firefighters in firefighting activities. Such strategies include adaptive response to changing conditions, coordination among multiple firefighters (i.e., agents) to converge on a common goal, balancing exploration and exploitation by maintaining diversity within the search space and adapting its parameters to navigate complex landscapes. To evaluate the performance of FFO, extensive experiments were conducted, wherein the FFO was examined against 13 commonly used optimization algorithms, namely, the Ant Colony Optimization (ACO), Bat Algorithm (BA), Biogeography-Based Optimization (BBO), Flower Pollination Algorithm (FPA), Genetic Algorithm (GA), Grey Wolf Optimizer (GWO), Harmony Search (HS), Particle Swarm Optimization (PSO), Simulated Annealing (SA), Tabu Search (TS), and Whale Optimization Algorithm (WOA), and across 24 benchmark functions, as well as 10 standard functions and 4 real engineering problems from the CEC 2020 suite. The results demonstrate that FFO achieves comparative performance and, in some scenarios, outperforms commonly adopted optimization algorithms in terms of the obtained fitness, time taken for exaction, and research space covered per unit of time. More specifically, FFO ranked first in the Distance per Unit Time metric and maintained a top 5 performance in higher dimensions (i.e., 20D and 50D).

Keywords: Optimization; Benchmarking; Metaheuristics.

1.0 Introduction

Metaheuristics play a large role in the domain of optimization. These algorithms have been renowned for their efficacy in tackling complex and multidimensional problems that can typically be beyond the reach of traditional methods [1]. Metaheuristics are distinguished by their flexibility and robustness, making them particularly suitable for problems where the solution landscape is rugged or poorly defined, such as those expected across diverse disciplines, ranging from engineering and logistics to economics and data science [2]. For example, metaheuristics' versatility enables their engineering application to optimize design parameters for complex systems. In logistics, metaheuristics can help solve scheduling and routing problems. Similarly, metaheuristics can prove beneficial in finance systems to optimize investment portfolios, to name a few.

Metaheuristics can be defined as high-level strategies that coordinate simpler investigative methodologies to explore and exploit the search space efficiently [3]. These strategies are characterized by their reliance on processes that promote some form of balance between

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

41 exploration of the search space to avoid entrapment in local optima and exploitation mechanisms
42 that refine promising areas to converge toward global optima [4]. Thus, metaheuristics can be
43 thought of as generic and adaptable to a broad spectrum of problems with minimal modification.
44 This can be advantageous to problem-specific algorithms.

45 Metaheuristics are broadly classified into two categories based on their approach: single-solution
46 based and population-based. Single-solution metaheuristics iteratively improve a single candidate
47 solution. These algorithms capitalize on the collective intelligence of the population to explore and
48 exploit the search space more broadly. Some such metaheuristics include Simulated Annealing
49 (SA) and Tabu Search (TS) [5]. This group of algorithms employs mechanisms to escape local
50 optima, like probabilistic acceptance of worse solutions in SA or using memory structures in TS
51 to avoid revisiting previously explored areas of the search space. The efficiency of single-solution
52 metaheuristics is tied to their ability to fine-tune a solution through mechanisms like adaptive
53 neighborhood searches and intensification strategies that home in on promising regions of the
54 search space [5].

55 On the other hand, population-based metaheuristics evolve a group (i.e., population) of solutions
56 to leverage interactions within this group to explore and exploit the search space collectively [6].
57 Some examples under this group include Genetic Algorithms (GA) and Particle Swarm
58 Optimization (PSO). Such algorithms can maintain diversity within the population and avoid
59 premature convergence to suboptimal solutions. For instance, GA employs operators such as
60 crossover and mutation to introduce variability and ensure robust exploration, while PSO mimics
61 social behaviors of swarms [7]. These two examples can balance exploration and exploitation
62 through the dynamic adjustment of particle velocities based on individual and collective
63 experiences. This population-based approach enables these algorithms to effectively navigate
64 complex, multimodal optimization landscapes by simultaneously exploring multiple regions of the
65 search space, increasing the likelihood of finding a global optimum. It goes without saying that
66 hybrid approaches that combine elements from both single-solution and population-based
67 metaheuristics have emerged as a means to leverage the strengths of both strategies [8]. These
68 hybrid methods often incorporate mechanisms like adaptive parameter control, multi-stage search
69 processes, and cooperative co-evolution to enhance performance on a wide range of optimization
70 problems [9].

71 Similarly, metaheuristics can also be classified based on their source of inspiration. Some
72 metaheuristics are nature-inspired algorithms, wherein they are inspired by natural phenomena,
73 biological processes, or behaviors observed in animals/plants. These nature-inspired algorithms
74 often mimic survival mechanisms, evolutionary processes, or social behaviors. For example, GA,
75 PSO, and Ant Colony Optimization (ACO) are representative of such classification. Then, some
76 metaheuristics draw inspiration from human behaviors, the physical world, and societal structures.
77 For instance, both TS and SA incorporate actions and behaviors seen in humans (i.e., memory)
78 and physical processes (i.e., annealing in metallurgy) [10].

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

79 Despite their versatility and ease of use, metaheuristics can suffer from challenges [11]. One such
80 challenge is drawing a balance between exploration and exploitation capabilities. These
81 capabilities can be crucial for avoiding premature convergence and ensuring the global optimum
82 is reached. Moreover, the stochastic nature of these algorithms often requires multiple runs to
83 achieve consistent results, which can be computationally expensive [12]. Fortunately, the field of
84 metaheuristics continues to grow in response to addressing increasingly complex problems
85 [13,14]. One notable trend is the hybridization of metaheuristic algorithms, where two or more
86 distinct strategies are combined to exploit their complementary strengths. For instance, hybrid
87 algorithms might combine one algorithm's explorative power with another's intensive exploitation
88 capabilities. Such hybridization can potentially yield solutions that are both diverse and precise.

89 Further, recent studies have proposed novel metaheuristic algorithms such as the Improved
90 Crowding Particle Algorithm (I-CPA) and the Tree Seed Algorithm (TSA) [15]. For instance, I-
91 CPA has been applied to optimize engineering design problems with multi-objectives and complex
92 constraints, improving the balance between exploration and exploitation [16]. Similarly, TSA,
93 inspired by tree seed dispersal mechanisms, has been successfully used in solving scheduling and
94 resource allocation problems [17]. These advancements highlight the ongoing evolution and
95 diversification of metaheuristic algorithms and showcase their adaptability to various domains. In
96 addition to these recent advancements, other metaheuristics such as the Harris Hawks Optimization
97 (HHO) and the Arithmetic Optimization Algorithm (AOA) have gained attention due to their
98 robust performance across a variety of domains [18,19]. HHO, inspired by the cooperative hunting
99 strategy of Harris hawks, has been applied to challenging problems, including engineering,
100 medical, data mining and clustering [20]. AOA, based on arithmetic operations, has also shown
101 success in solving complex mathematical and engineering optimization problems. These emerging
102 algorithms further underline the potential of metaheuristics in addressing diverse optimization
103 challenges, contributing to a growing repository of tools designed to tackle specific industrial and
104 research needs [19].

105 Still, as computational challenges grow and the need for efficient optimization strategies
106 intensifies, the role of metaheuristics becomes increasingly important and warranted. The ability
107 of metaheuristics to adapt and provide feasible and efficient solutions. The above motivates this
108 work wherein we propose a novel algorithm, Firefighter Optimization (FFO), for optimization
109 problems that could be applied in various areas (e.g., a general purpose algorithm). FFO is
110 motivated by the strategies and tactics employed by firefighters, such as the dynamic distribution
111 of resources, adaptive responses to evolving conditions, and coordinated efforts among multiple
112 firefighters (agents) to achieve a unified objective. FFO also balances exploration and exploitation
113 by maintaining diversity within the search space and adjusting its parameters to navigate complex
114 optimization challenges. A number of comparative experiments, supplemented with various
115 metrics, were carried out to validate the effectiveness and competitiveness of FFO. More
116 specifically, the performance of FFO and the other selected algorithms was examined across over

117 600 tests on a wide range of benchmark and test functions. Our experimental results demonstrate
118 the effectiveness and competitiveness of FFO compared to state-of-the-art algorithms.

119 The rest of the paper is organized as follows: Section 2 presents a description of FFO and explains
120 each component in detail. Sections 3 and 4 describe the aforementioned algorithms and 24
121 commonly used benchmarking test functions for various complexity levels. Finally, Sections 4 and
122 5 conclude the paper with a presentation of our comparative results and conclusions/findings
123 learned from our analysis.

124 **2.0 Description of the Firefighter Optimization (FFO) algorithm**

125 This section describes the FFO in more detail (see flowchart in Fig. 1). We start with a general
126 description and then dive into a more detailed analysis of FFO's functions.

127 *2.1 General description*

128 The Firefighter optimization (FFO) algorithm is inspired by the strategies and tactics used by
129 firefighters to combat fires in real-world scenarios. In the face of a fire, firefighters must
130 strategically allocate resources, decide when to focus on extinguishing the flames, and when to
131 protect specific areas or perform rescue operations. More specifically, this optimization technique
132 draws from various aspects of firefighting, including the dynamic allocation of resources, adaptive
133 response to changing conditions, and coordination among multiple firefighters (i.e., agents) to
134 achieve a common goal. Further, the FFO algorithm is designed to balance exploration and
135 exploitation by maintaining diversity within the search space and adapting its parameters to
136 navigate complex optimization landscapes. See Table 1 for a comparison of this algorithm against
137 other commonly used in optimization.

138 Initialization: The algorithm starts by randomly initializing a population of agents within the
139 specified bounds of the search space. Each agent represents a potential solution to the optimization
140 problem.

141 Evaluation: Each agent's position is evaluated using the objective function, which measures the
142 fitness or quality of the solution. The best agent, i.e., the one with the lowest fitness value for
143 minimization problems, is identified as the global best solution.

144 Adaptive Local Search: The FFO algorithm employs an adaptive local search mechanism to refine
145 the positions of the agents. This process involves generating perturbations around the current
146 position of an agent and evaluating the new positions. The perturbations are adjusted adaptively
147 based on the agent's performance and the iteration count. This local search helps agents escape
148 local optima and explore the solution space more effectively.

149 Crossover and Mutation: To enhance diversity and promote exploration, the FFO algorithm
150 incorporates crossover and mutation operators. The crossover operator allows agents to exchange
151 information, creating new solutions by combining parts of two parent agents. The mutation

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

152 operator introduces random changes to an agent's position, providing an additional mechanism to
153 explore new areas of the search space.

154 Perturbation Mechanism: When agents fail to improve over a certain number of iterations, a
155 perturbation mechanism is triggered. This mechanism mimics the adaptive response of firefighters
156 to changing conditions. Agents undergo a larger perturbation, guided by the global best agent, to
157 move towards potentially better regions of the search space. The intensity of the perturbation
158 increases with the number of unsuccessful iterations, allowing the algorithm to escape stagnation
159 and continue searching for optimal solutions.

160 Adaptive Step Size: The step size used in the local search and perturbation mechanisms is
161 adaptively adjusted based on the algorithm's progress. If the algorithm detects stagnation, the step
162 size is increased to encourage exploration. Conversely, if the algorithm is converging towards a
163 solution, the step size is reduced to fine-tune the search and improve solution accuracy.

164 Cooling Schedule: The FFO algorithm incorporates a cooling schedule inspired by simulated
165 annealing. The temperature parameter, which controls the acceptance probability of worse
166 solutions during the local search, is gradually reduced over iterations. This allows the algorithm to
167 initially explore more freely and then gradually focus on exploitation as it approaches
168 convergence.

169 Termination Criteria: The algorithm runs until one or more termination criteria are met. These
170 criteria can include reaching a maximum number of iterations, exceeding a predefined number of
171 iterations without improvement, or achieving a target fitness value. The termination criteria ensure
172 that the algorithm does not run indefinitely and provides a solution within a reasonable time frame.

175 2.2 Detailed description

176 A more detailed description of FFO's functions is provided herein.

177 Initialization (`__init__`)

178 The initialization function (`__init__`) of the FirefighterOptimization class sets up the algorithm's
179 parameters, agents, and initial conditions for optimization. These parameters include the objective
180 function, dimensions of the problem, number of agents, maximum iterations, no-improvement
181 limit, and bounds for the search space. Additional parameters stemming from existing algorithms
182 for crossover, mutation, simulated annealing, and perturbation control are also set up. The agents
183 (i.e., solutions) are initialized randomly within the specified bounds, and the best global agent and
184 fitness are identified at the start.

185 **Initialization Process:**

186 The process can be broken down into the following steps:

187 Parameter Setup

188 Agents Initialization: Agents are randomly distributed within the bounds:

189 Best Agent Identification: The initial best global agent and its fitness are determined:

190 Other Parameters: Additional parameters like step size, mutation rates, and counters are initialized:

191 **Agent Evaluation** (`evaluate_agents`)

192 The `evaluate_agents` function assesses the fitness of each agent within the initiated population.
193 This function updates the best global fitness and agent if/when a better solution is found. This
194 function calculates the fitness of each agent based on the objective function and updates the global
195 best agent if an improved solution is identified. This evaluation process also guides the algorithm's
196 search process toward better solutions. Mathematically, the evaluation involves computing the
197 objective function for each agent and identifying the agent with the minimum fitness value.

198 Objective Function, $f(x)$: The function to be minimized and is evaluated for each agent x_i .

199 Fitness Calculation: For each agent x_i , the fitness is $f(x_i)$.

200 Best Fitness Update: The global best fitness and agent are updated if a new minimum is found.

201 Evaluation Process

202 The evaluation process can be broken down into the following steps:

203 Fitness Calculation

204 Best Agent Identification

205 Return Fitness Values

206 **Agent Update** (`update_agents`)

207 The `update_agents` function is responsible for evolving the population of firefighters (i.e., agents)
208 to maintain diversity through crossover, mutation, and perturbation operations. This function
209 involves modifying agent positions in the solution space to explore new regions. As inspired by
210 genetic algorithms, this function applies crossover to combine traits from different agents,

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

211 mutation¹ to introduce random changes, and perturbations to escape local optima. Mathematically,
212 the update process includes the following key components:

213 Crossover Operation

214 Mutation Operation

215 Perturbation Operation

216 Update Process: The update process involves the following steps:

217 *Evaluate Agents*: The fitness of agents is then evaluated to update the global best fitness achieved:

218 *Crossover and Mutation*: Each agent undergoes crossover and mutation based on set probabilities:

219 *Perturbation*: If no improvement is observed for an extended period, this function applies
220 perturbations:

221 *Boundary Check*: Agents are clipped within the bounds:

222 *Trajectory and Perturbation History*: Updates to agents are recorded for trajectory analysis
223

224 **Local Search** (local_search)

225 The local_search function refines an agent's position by exploring its neighborhood. This function
226 helps agents escape local optima and find better solutions. This function involves making small
227 adjustments to an agent's position to find a better solution in its vicinity. The process is guided by
228 a temperature parameter, allowing the acceptance of worse solutions early on to escape local
229 optima. As the temperature decreases, the search becomes more focused on local refinement – in
230 a similar process to controlling fires. Mathematically, local search applies perturbations to an
231 agent's position and evaluates the new positions. The acceptance of new positions is probabilistic,
232 influenced by a temperature parameter.

233 Perturbation

234 Temperature

235 Acceptance Probability

236 Local Search Process: The process involves the following steps:

237 *Temperature Calculation*: The temperature is calculated based on the iteration:

238 *Local Best Initialization*: The current agent is considered the local best:

239 *Perturbation and Evaluation*: Small adjustments are made to the agent's position, and new positions
240 are evaluated:

241 *Acceptance Check*: New positions are accepted based on fitness improvement or probabilistically:

242 *Return Local Best*: The refined local best position is then returned:

243 **Perturbation Application** (apply_perturbation)

244 Perturbation application is a strategy to escape local optima by making larger adjustments to
245 agents' positions, which can be particularly useful when the algorithm stagnates. The
246 apply_perturbation function introduces significant changes to agents' positions based on the global
247 best agent when no improvement is observed. In mathematical notation, perturbation involves
248 adjusting an agent's position towards the global best agent, scaled by an intensity factor, such that:

249 Direction Vector:

250 Perturbation:

¹ Further information on these operations will be provided in a subsequent section.

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

251 Perturbation Process

252 The process involves the following steps:

253 *Direction Calculation:* The direction vector from the agent to the global best is calculated:

254 *Perturbation Calculation:* A perturbation is applied based on the direction vector and intensity:

255 *New Position Calculation:* The agent's new position is calculated:

256 **Crossover** (crossover)

257 The crossover function combines parts of two agents to create new agents as a means of
258 introducing diversity into the initialized population. This genetic algorithm-inspired method helps
259 explore new solutions by recombining existing ones. Key components in this function include:

260 Crossover Point

261 New Agents

262 Crossover Process: The process involves the following steps:

263 *Crossover Point Selection:* A random crossover point is selected:

264 *Agent Combination:* New agents are created by combining segments of the parent agents:

265 *Return New Agents:* The new agents are returned:

266 **Cooling Schedule** (cooling_schedule)

267 The cooling_schedule function adjusts the step size based on the algorithm's progress, similar to
268 the *cooling* option in simulated annealing. The cooling schedule involves gradually reducing the
269 step size as the algorithm progresses (in a similar manner to controlling the fire toward the later
270 stages of firefighting). This process allows for a finer search of the solution space over time,
271 balancing exploration and exploitation. Mathematically, the cooling schedule involves updating
272 the step size based on the number of iterations and the no-improvement counter such that:

273 Step Size Update:

274 The step size is reduced based on a cooling factor.

275 Cooling Process:

276 The process involves the following steps:

277 *Step Size Adjustment:* The step size is adjusted based on the no-improvement counter:

278

279 **Execution Loop** (run)

280 The run function controls the main execution loop of the algorithm, where agents are updated,
281 evaluated, and the cooling schedule is applied until a termination condition is met. It also tracks
282 the best solution and its fitness across iterations. The execution loop is the core of the optimization
283 process. It iteratively updates agents, evaluates their fitness, applies the cooling schedule, and
284 checks termination conditions. This loop continues until the optimization criteria are met, ensuring
285 that the algorithm converges to an optimal solution. Mathematically, the execution loop involves
286 iterating over the update and evaluation processes while tracking the best solution. Key
287 components include:

288 Execution Process

289 The process involves the following steps:

290 *Initialization:* The fitness history and trajectory are initialized

291 *Main Loop:* The main loop iterates until the termination condition is met

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

292 *Return Best Solution:* The best global agent and fitness are returned

293 **Termination Check** (should_terminate)

294 The should_terminate function determines whether the algorithm should stop based on several
295 conditions: *maximum iterations reached*, *no improvement for a set number of iterations*, or
296 *achieving a target fitness level*. Thus, this function ensures that the algorithm terminates when
297 further exploration is unlikely to yield better results.

298 Iteration Check: The algorithm stops if the maximum number of iterations is reached (i.e., $k \geq \text{max_iter}$).

299 No Improvement Check: The algorithm stops if no improvement is observed for a set number of iterations.

300 Target Fitness Check: The algorithm stops if the target fitness level is achieved.

301 Termination Process

302 The process involves the following steps:

303 *Condition Check:* The termination condition is evaluated based on the iteration, no-improvement
304 counter, and best global fitness

305 *Return Condition:* The termination condition is returned

306 **Execution Time** (get_execution_time)

307 The get_execution_time function calculates the total runtime of the algorithm as a means to
308 present a measure for evaluating the time efficiency of the algorithm. This execution time is
309 calculated as the difference between the end time and the start time.

310 **Trajectory Tracking** (get_trajectory)

311 The get_trajectory function records the sequence of solutions explored by the algorithm, which
312 can be further analyzed to examine the search behavior and pathway through the solution space.
313 The trajectory involves recording the positions of agents over time.

314 **Total Distance Traveled** (get_total_distance)

315 The get_total_distance function computes the cumulative distance traveled by the algorithm in the
316 solution space. Such a distance can be an indicator of the algorithm's exploratory behavior and
317 efficiency. The total distance traveled involves summing the Euclidean distances between
318 consecutive positions of agents.

462 **3.0 Description of benchmarking algorithms, experiments, and functions**

463 This section describes the experimental examination used to benchmark FFO. For a start, FFO was
464 examined against 13 other commonly used optimization algorithms, namely, the Ant Colony
465 Optimization (ACO), Bat Algorithm (BA), Biogeography-Based Optimization (BBO), Cuckoo
466 Search (CS), Firefly Algorithm (FA), Flower Pollination Algorithm (FPA), Genetic Algorithm
467 (GA), Grey Wolf Optimizer (GWO), Harmony Search (HS), Particle Swarm Optimization (PSO),
468 Simulated Annealing (SA), Tabu Search (TS), and Whale Optimization Algorithm (WOA). All of
469 these algorithms were used in their default settings², and a brief description of each is presented
470 herein for completion. We invite interested readers to review the original publications for these
471 algorithms to learn more about their settings and applications.

472 *3.1 Ant Colony Optimization (ACO)*

473 The Ant Colony Optimization (ACO) was formulated by Dorigo and colleagues [21] based on the
474 pheromone-laying behavior observed in certain ant species. This method uses ants as artificial
475 agents to simulate the decision-making process of real ants in selecting paths. As ants traverse
476 paths, they deposit pheromones that guide subsequent ants toward promising solutions. The ACO
477 algorithm is a probabilistic approach to problem-solving where the search space is represented as
478 a graph, and paths through this graph are evaluated based on the intensity of pheromone deposits.
479 The algorithm's efficiency hinges on several parameters: alpha (influence of pheromone on path
480 selection, set at 1.0), beta (influence of heuristic information on path choice, set at 2.0), and rho
481 (rate of pheromone evaporation, set at 0.5). This algorithms has been successfully applied to
482 network routing, scheduling, and other optimization problems that involve finding optimal paths
483 through graphs [22].

484 *3.2 Bat Algorithm (BA)*

485 Developed by Yang et al. in 2012 [23], the Bat Algorithm (BA) was designed to mimic the
486 echolocation behavior of bats. This algorithm models bats that emit sound waves to navigate and
487 locate prey, translating this biological mechanism into a search and optimization strategy. In BA,
488 each simulated bat adjusts its flight based on velocity, loudness, and echolocation frequency,
489 which dynamically changes from exploration to exploitation phases depending on the proximity
490 to optimal solutions. Key parameters of BA include alpha (initial loudness, set at 0.5), gamma (rate
491 of loudness decrease and emission rate increase, set at 0.5), and frequency range (f_{\min} at 0, f_{\max} at
492 2.0). BA is adept at tackling complex problems characterized by continuous and multimodal search
493 spaces and has shown effectiveness in engineering design and dynamic optimization tasks [24].

² The default setting for FFO include:

FirefighterOptimization:

```
def __init__(self, objective_func, dimension, num_agents=100, max_iter=500, no_improve_limit=30, bounds=(-5.12, 5.12), step_size=1.0, crossover_probability=0.5, mutation_probability=0.1, initial_temp=100.0, cooling_rate=0.95, verbose=False, use_additional_conditions=False, target_fitness=1e-5):
```

494 3.3 Biogeography-Based Optimization (BBO)

495 Introduced by Simon in 2008 [25], Biogeography-Based Optimization (BBO) leverages migration
496 concepts from biogeography to solve optimization problems. BBO operates on the premise that
497 species migrate between habitats, affecting their survival and reproduction rates. The algorithm
498 features migration operators that simulate gene flow by exchanging solution features, akin to
499 species migration in nature. Key components include the habitat suitability index, which evaluates
500 the desirability of solutions, and migration rates that determine the exchange intensity between
501 solutions. BBO also uses mutation to enhance genetic diversity and avoid premature convergence
502 on suboptimal solutions. The BBO algorithm has proven effective in network design, power
503 systems optimization, and other applications where geographic considerations are crucial [26].

504 3.4 Cuckoo Search (CS)

505 Cuckoo Search (CS) was developed by Yang and Deb [27]. This algorithm is inspired by the
506 obligate brood parasitism of some cuckoo species by laying their eggs in the nests of other host
507 birds. If a host bird discovers the eggs are not its own, it will either throw them away or abandon
508 its nest. The algorithm uses this idea to lay a new solution (egg) into a randomly chosen nest, and
509 the best nests with high-quality eggs will be carried over to the next generations. CS is known for
510 its simplicity and flexibility. It has been effectively applied in solving problems like structural
511 design, scheduling, and routing problems where the search space is discrete, and the global
512 optimum is hidden among many local optima [28].

513 3.5 Firefly Algorithm (FA)

514 The flashing behavior of fireflies inspires the Firefly Algorithm (FA). Such a flashing behavior
515 acts as a signal system to attract other fireflies. FA, developed by Yang in 2008 [29], uses these
516 biologically inspired techniques to handle optimization problems and functions. Fireflies in the
517 algorithm search the space by moving towards brighter and more attractive fireflies. The
518 attractiveness is proportional to the brightness, and both decrease as their distance increases. The
519 landscape of the objective function determines the brightness of a firefly. A key advantage of FA
520 is its ability to deal with multimodal optimization problems, as it naturally divides the population
521 into subgroups that converge to different optima. Some of the key settings in the FA algorithm
522 include alpha (a randomness factor that affects the movement of a firefly and helps fireflies explore
523 the search space beyond the immediate neighboring fireflies, selected at 0.5), beta (controls how
524 strongly other fireflies are drawn towards it, selected at 1.0), and gamma (influences how the
525 attractiveness of a firefly decreases with distance, selected at 1.0). This feature makes it
526 particularly useful for complex functions with multiple local optima. FA has been applied to
527 problems like economic dispatch, clustering, and image processing [30].

528 3.6 Flower Pollination Algorithm (FPA)

529 Devised by Yang et al. in 2012 [31], the Flower Pollination Algorithm (FPA) algorithm emulates
530 the natural pollination processes of flowers. It aims to optimize solutions by alternating between
531 self-pollination and cross-pollination mechanisms that are naturally facilitated by natural vectors
532 like insects, wind, or water. This approach maintains solution diversity and promotes effective

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

533 convergence. In FPA, solutions are represented as flowers whose attractiveness—determined by
534 fitness—guides the pollination process. The algorithm uses local pollination for minor adjustments
535 within the immediate search area and global pollination, employing Levy flights for broader
536 searches to escape local optima. FPA's dual strategy has been effectively applied to engineering
537 design and economic load dispatch challenges [32].

538

539 *3.7 Genetic Algorithm (GA)*

540 Holland [33] formulated the Genetic Algorithm (GA) as a computational analog to natural
541 selection, embodying the principle of survival of the fittest. GA begins with a population of
542 randomly generated individuals, evolving over generations to optimize solutions. Selection is
543 fitness-based, favoring solutions that perform better under a defined fitness function. GA
544 incorporates mutation and crossover as genetic operators to introduce variability and new traits
545 into offspring. Typical parameters include a population size of 100, a mutation rate of 0.1, and a
546 crossover rate of 0.1. This algorithm is widely utilized across fields such as optimization, automatic
547 programming, and machine learning, where it helps solve complex problems efficiently [34].

548 *3.8 Grey Wolf Optimizer (GWO)*

549 The Grey Wolf Optimizer (GWO), introduced by Mirjalili et al. in 2014 [35], is a nature-inspired
550 metaheuristic algorithm inspired by grey wolves' social structure and hunting behavior. Grey
551 wolves exhibit a distinct hierarchical system consisting of alpha, beta, delta, and omega wolves,
552 with each tier playing a specific role within the pack. In GWO, this hierarchy is mirrored in the
553 solution process: the alpha wolf represents the optimal solution, followed by beta and delta as the
554 second and third best solutions, respectively, while omega wolves embody the remaining candidate
555 solutions. The algorithm leverages this structure to simulate the wolves' hunting strategy, which is
556 segmented into three phases: tracking, encircling, and attacking prey, each reflecting a critical
557 phase of the optimization process. GWO is adept at navigating complex, multidimensional
558 landscapes, making it valuable in fields such as mechanical engineering design and renewable
559 energy optimization, where the search spaces often exhibit high nonlinearity and multimodality.

560 *3.9 Harmony Search (HS)*

561 Developed by Geem et al. in 2001 [36], Harmony Search (HS) is an optimization algorithm
562 inspired by the improvisational process of musicians tuning their instruments to achieve aesthetic
563 harmony. This algorithm iteratively adjusts solution vectors in a similar fashion to musicians'
564 adjust pitches to optimize a given function. HS employs a stochastic approach rather than a
565 gradient-based method, enhancing its efficacy in addressing non-differential and discrete
566 problems. The algorithm's performance is governed by two primary parameters: the harmony
567 memory consideration rate (set at 0.9), which dictates the likelihood of selecting existing memory
568 solutions for new harmonies, and the pitch adjustment rate (set at 0.3), which determines how
569 much the chosen solutions are modified. HS has shown significant utility in solving complex
570 engineering problems such as structural and water network design, where traditional methods may
571 struggle due to the extensive search spaces involved.

572 3.10 Particle Swarm Optimization (PSO)

573 Particle Swarm Optimization (PSO) was introduced by Kennedy and Eberhart in 1995 [37]. This
574 algorithm simulates the social behaviors observed in flocks of birds or schools of fish. This
575 metaheuristic optimizes problem solutions by iteratively enhancing a population of candidate
576 solutions based on the personal and collective experiences of the particles. For example, the PSO
577 starts with randomly initialized particles (solutions) and updates their positions within the search
578 space by balancing personal best achievements and global knowledge shared across the swarm.
579 The algorithm is known for its simplicity and adaptability, often requiring few parameter
580 adjustments. It utilizes three key parameters: swarm size (typically 100 particles), cognitive
581 coefficient (influence of the particle's own memory, set at 1.0), and social coefficient (influence
582 of neighboring particles, also set at 1.0). These factors influence the dynamics of particle
583 movements towards optimal solutions. PSO is particularly effective in continuous, high-
584 dimensional environments and has been applied successfully across various domains, including
585 electrical power systems, robotics, and bioinformatics [38].

586 3.11 Simulated Annealing (SA)

587 Simulated Annealing (SA) was developed by Kirkpatrick et al. in 1983 and Cerny in 1985 [39].
588 This is a probabilistic method designed to approximate the global optimum of a function. SA is
589 inspired by the metallurgical process of annealing, where materials are heated and then gradually
590 cooled to improve their structural properties. This process is mimicked by allowing a system to
591 explore higher energy states (solutions) by heating, thereby overcoming local optima, followed by
592 slow cooling to stabilize at a lower energy state (optimal solution). The algorithm makes random
593 transitions to neighboring solutions, accepting improvements outright and worse solutions based
594 on a decreasing probability over time. Key parameters include the initial temperature (set at 100)
595 and cooling rate (set at 0.95). SA has been successfully applied across various domains, from
596 economics to computational science [40].

597 3.12 Tabu Search (TS)

598 Tabu Search (TS) was introduced by Glover in the late 1980s [41] as a metaheuristic that extends
599 beyond local search methods. TS extends such methods by adopting a memory structure, the tabu
600 list, to avoid cycling back to previously encountered suboptimal solutions. This list temporarily
601 bans certain moves, helping the algorithm to escape local optima and explore less favorable
602 solutions that might lead to a globally optimal solution. TS is adaptable, allowing periodic resetting
603 of the tabu status to balance exploration and exploitation. It is particularly effective in complex
604 scheduling, logistical planning, and assignment problems, where its ability to navigate challenging
605 solution spaces is applications [42].

606 3.13 Whale Optimization Algorithm (WOA)

607 The Whale Optimization Algorithm (WOA) was developed by Mirjalili and Lewis in 2016 [43].
608 The WOA draws inspiration from the bubble-net feeding behavior of humpback whales. This
609 algorithm simulates the whales' strategies of encircling prey and using a spiral path to close in,
610 which are mirrored in the shrinking encircling mechanism and spiral updating position phases of

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

611 the algorithm. These methods allow the WOA to balance exploration and exploitation
612 dynamically, making it adept at handling complex, non-separable, and nonlinear optimization
613 problems. WOA's effectiveness is demonstrated in its applications across mechanical design and
614 industrial engineering, where it optimizes a variety of challenging problem landscapes [44].

615 **4.0 Description of utilized benchmarking functions**

616 This section describes 24 benchmark functions commonly used in benchmarking analysis.

617 *4.1 Ackley Function*

618 The Ackley function has a two-dimensional form with a relatively uniform plane [45]. This
619 function also has several dozen local minimums and one global extreme of significantly smaller
620 value than most of the local minimums. This function allows very efficient testing of optimization
621 algorithms as regards stopping at local extremes. The Ackley function is designed to test the ability
622 of optimization algorithms to escape local minima and converge towards a global minimum in a
623 complex landscape. The global minimum is at $x=0$ where $f(x)=0$. This function has the following
624 form:

$$625 \quad f(x) = -20 \exp\left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^n x_i^2}\right) - \exp\left(\frac{1}{n} \sum_{i=1}^n \cos(2\pi x_i)\right) + 20 + e \quad \text{Eq. 1}$$

626 *4.2 Alpine Function*

627 The Alpine function is a multimodal and non-smooth function and hence can provide significant
628 challenges in terms of local minima and ruggedness tests [46]. This function examines the ability
629 of optimization algorithms to handle non-differentiable points with abrupt changes. The global
630 minimum for this function occurs at $x=0$ where $f(x)=0$. This function can be useful for testing
631 optimization algorithms in real-world problems involving non-smooth dynamics, such as
632 mechanical systems with friction or other resistive forces. This function has the following form:

$$633 \quad f(x) = \sum_{i=1}^n |x_i \sin(x_i) + 0.1x_i| \quad \text{Eq. 2}$$

634 *4.3 Booth's Function*

635 This function presents a simple test case for algorithm testing with a convex with a single global
636 minimum at $(x,y) = (1,3)$ where $f(x,y) = 0$. This function has the following form:

$$637 \quad f(x,y) = (x + 2y - 7)^2 + (2x + y - 5)^2 \quad \text{Eq. 3}$$

638 *4.4 Cross-in-Tray Function*

639 This function is known for its challenging landscape, characterized by a high degree of
640 multimodality [47]. The function contains several deep holes, indicative of global minima, which
641 are located symmetrically in the function's domain, and may present a significant challenge in the
642 convergence process of algorithms to navigate complex landscapes and avoid local minima in
643 favor of locating and confirming global minima. The global minima occur at approximately
644 $(x,y)=(1.34941,-1.34941),(-1.34941,1.34941),(1.34941,1.34941),(-1.34941,-1.34941)$ with
645 $f(x,y) \approx -2.06261$. This function has the following form:

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

$$f(x, y) = -0.0001 \left(\left| \sin(x) \sin(y) \exp \left(\left| 100 - \frac{\sqrt{x^2 + y^2}}{\pi} \right| \right) + 1 \right| \right)^{0.1} \quad \text{Eq. 4}$$

4.5 Drop-Wave Function

This function features a rippled wave surface that turn challenging to optimize due to its frequent local minima and a pronounced global minimum [48]. This is a multimodal function with a global minimum at $(x,y)=(0,0)$ where $f(x,y)=-1$. It tests an algorithm's capability to navigate through frequent oscillations to find the lowest point and is particularly relevant for simulations and optimizations in fields involving vibrational analysis and wave propagation (i.e., acoustics and materials science, etc.). This function has the following form:

$$f(x, y) = -\frac{1 + \cos(12\sqrt{x^2 + y^2})}{0.5(x^2 + y^2) + 2} \quad \text{Eq. 5}$$

4.6 Easom Function

The Easom function is a highly unimodal benchmark function stemming from its narrow global peak that is surrounded by a flat landscape [49]. This function has a constant plane over the vast majority of the domain with one global minimum, at $(x,y)=(\pi,\pi)$ where $f(x,y)=-1$, that is difficult to locate due to the flatness of the surrounding area. Oftentimes, this function is used in testing the precision and convergence characteristics of optimization algorithms, and their ability to hone in on and precisely converge to a sharply defined minima. This function has the following form:

$$f(x, y) = -\cos(x) \cos(y) \exp(-((x - \pi)^2 + (y - \pi)^2)) \quad \text{Eq. 6}$$

4.7 Eggholder Function

The Eggholder function has a highly irregular and complex surface characterized by an uneven plane with several local minimums (of values like its only global minimum) [50,51]. The global minimum is found at $(x,y)=(512,404.2319)$ where $f(x,y)\approx-959.6407$. This function is frequently used in benchmarking sophisticated global optimization algorithms, especially those intended to solve rugged and unpredictable landscape-based problems. This function has the following form:

$$f(x, y) = -(y + 47) \sin \left(\sqrt{\left| \left(\frac{y+x}{2+47} \right) \right|} \right) - x \sin(\sqrt{|x - (y + 47)|}) \quad \text{Eq.7}$$

4.8 Expanded Schaffer's F6 Function

This is an expansion of the original Schaffer's function that hopes to test for algorithm effectiveness over a broader area with a more complex landscape. More specifically, the function is highly multimodal and oscillatory and hence presents a significant challenge in identifying the global minimum amidst numerous local minima. The function has a global minimum at $(x,y)=(0,0)$ where $f(x,y)=0$. This function can be used in testing spatial algorithms that may be applied in fields like geographic information systems and molecular dynamics where spatial relationships and dynamics are crucial.

$$f(x) = 0.5 + \frac{\sin^2(\sqrt{x^2+y^2})-0.5}{[1+0.001(x^2+y^2)]^2} \quad \text{Eq. 8}$$

4.9 Expanded Zakharov Function

This is an extension of the Zakharov function [46] and provides a more challenging scenario for testing optimization algorithms by combining linear, quadratic, and quartic terms. This function has a single global minimum at $x=0$ where $f(x)=0$. This function is used to evaluate the performance of large-scale optimization algorithms in areas such as financial modeling and energy systems, where complex interactions between variables are common.

$$f(x) = \sum_{i=1}^n x_i^2 + (\sum_{i=1}^n 50ix_i)^2 + (\sum_{i=1}^n 50ix_i)^4 \quad \text{Eq. 9}$$

4.10 Goldstein-Price Function

This function was created by Goldstein and Price [52] to provide a multimodal complex landscape with sharp peaks and valleys. The same function has several local minima and a global minimum found at $(x,y) = (0,-1)$ with $f(x,y) = 3$. This function has the following form:

$$f(x,y) = [1 + (x + y + 1)^2(19 - 14x + 3x^2 - 14y + 6xy + 3y^2)] \times [30 + 2(sx - 3y)^2(18 - 32x + 12x^2 + 48y - 36xy + 27y^2)] \quad \text{Eq. 10}$$

4.11 Griewank Function

The Griewank function has large, flat areas interrupted by periodic narrow, deep valleys [53]. This function is highly multimodal and oscillatory and can challenge the algorithm's ability to find the global minimum (at $x=0$) amidst frequent changes in gradient. It is particularly used to test the efficiency of algorithms in handling complex oscillations and multimodal functions with application within acoustic waveguides design and structural engineering with regard to vibrations. This function has the following form:

$$f(x) = 1 + \sum_{i=1}^n \frac{x_i^2}{4000} - \prod_{i=1}^n \cos(x_i/\sqrt{i}) \quad \text{Eq. 11}$$

4.12 Himmelblau's Function

Developed by Himmelblau [54], this function is characterized by multiple global minima, which makes it interesting for testing the robustness of optimization algorithms to locate and distinguish between multiple optima within a complex landscape. This function has four identical global minima located at $(x,y)=(3,2),(-2.805118,3.131312),(-3.779310,-3.283186),(3.584428,-1.848126)$ where $f(x,y)=0$. This function has the following form:

$$f(x,y) = (x^2 + y - 11)^2 + (x + y^2 - 7)^2 \quad \text{Eq. 12}$$

4.13 Holder Table Function

The Holder Table function features several deep and narrow global minima and is designed to challenge optimization algorithms in finding and recognizing global solutions in a multimodal space [55]. The function's global minima are symmetrically located around the origin, with four

712 known global minima where $f(x,y)=-19.2085$. This function can serve as a good evaluation metric
713 for multimodal optimization capabilities in logistics and routing problems where multiple
714 equivalent optimal routes need to be evaluated. This function has the following form:

$$715 \quad f(x, y) = - \left| \sin(x) \cos(y) \exp \left(\left| 1 - \frac{\sqrt{x^2+y^2}}{\pi} \right| \right) \right| \quad \text{Eq. 13}$$

716 *4.14 Levy Function N.13*

717 This is a variant to the Levi function. This variant is designed to test algorithms against steep
718 gradients and local optima. More specifically, this function has steep ridges and a complex global
719 structure with a global minimum at $(x,y)=(1,1)$ where $f(x,y)=0$. The Levi can be useful in
720 examining algorithms that need to handle sudden changes in gradient effectively. This function
721 has the following form:

$$722 \quad f(x, y) = \sin^2(3\pi x) + (x - 1)^2(1 + \sin^2(3\pi y)) + (y - 1)^2 (1 + \sin^2(2\pi y)) \quad \text{Eq. 14}$$

723 *4.15 Matyas Function*

724 This function was created by Matyas [56] as convex function that could serve as an elementary
725 test case for basic functionality and efficiency of optimization algorithms in a controlled setting.
726 The Matyas function has a global minimum at $(x,y) = (0,0)$ where $f(x,y)=0$. This function has the
727 following form:

$$728 \quad f(x, y) = 0.26(x^2 + y^2) - 0.48xy \quad \text{Eq. 15}$$

729 *4.16 Michalewicz Function*

730 This function was created by Michalewicz [57] to be especially difficult for evolutionary
731 algorithms to solve. This function is highly multimodal, with sharp peaks and valleys that are
732 sensitive to the variable m , which controls the steepness of the valleys and ridges. The function's
733 global minimum becomes more difficult to locate as m increases (with a typical value of $m=10$).
734 This function can be used in the testing and development of genetic and evolutionary algorithms,
735 particularly effective for applications requiring high precision in aerodynamics and biomechanical
736 engineering. This function has the following form:

$$737 \quad f(x) = - \sum_{i=1}^n \sin(x_i) \sin^{2m} \left(\frac{ix_i^2}{\pi} \right) \quad \text{Eq. 16}$$

738 *4.17 Rastrigin Function*

739 This function is named after Rastrigin [58] and presents an example of a highly non-linear
740 multimodal function with frequent local minima. The global minimum is at $x=0$ where $f(x)=0$.
741 The function is particularly designed to test the algorithm's capability to escape local minima and
742 is widely used in the testing and development of algorithms in evolutionary computation and real-
743 world scenarios where noise and local minima are prevalent, such as in electronic circuit design.
744 This function has the following form:

$$745 \quad f(x) = 10n + \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i)] \quad \text{Eq. 17}$$

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

746 4.18 Rosenbrock Function

747 This function was designed by Rosenbrock in 1960 as a non-linear and non-convex function to
748 test the performance of optimization algorithms over rugged terrain with a narrow, curved valley
749 leading to a global minimum [59]. This function has a global minimum inside a long, narrow,
750 parabolic shaped flat valley. In general, finding the valley is straightforward but converging to the
751 global minimum is difficult. A common multidimensional generalization of this function has the
752 following form:

$$753 f(x) = \sum_{i=1}^{n-1} [100(x_{i+1} - x_i^2)^2 + (1 - x_i)^2] \quad \text{Eq. 18}$$

754 4.19 Schaffer Function N. 2

755 This function is a variant belonging to the family of functions introduced by Schaffer, which are
756 used to evaluate the performance of optimization algorithms in handling oscillating landscapes
757 with narrow valleys [60]. The function is non-convex and multimodal, with a global minimum at
758 $(x,y)=(0,0)$ where $f(x,y)=0$. This variant can be sensitive to initial conditions due to the presence
759 of sharp peaks and deep valleys. This function has the following form:

$$760 f(x, y) = 0.5 + \frac{\sin^2(x^2 - y^2) - 0.5}{[1 + 0.001(x^2 + y^2)]^2} \quad \text{Eq. 19}$$

761 4.20 Schwefel Function

762 The Schwefel function is a classic optimization test problem introduced by Schwefel [61]. This
763 function is initially created for evolutionary algorithms and has complex and non-linear large
764 number of local minima (with a global minimum located near the bounds of the search space at
765 $x=(420.9687, \dots, 420.9687)$ where $f(x) \approx 0$). This function can be helpful in fields such as
766 aerospace for optimizing the shapes and trajectories of dynamic flying bodies. This function has
767 the following form:

$$768 f(x) = 418.9829n - x_i \sin(\sqrt{|x_i|}) \quad \text{Eq. 20}$$

769 4.21 Sphere Function

770 The Sphere function is one of the classical and simplest benchmark functions often used to test
771 preliminary optimization algorithms in terms of convergence and accuracy. The Sphere function
772 is continuous, convex, and unimodal with a global minimum at $x^* = 0$ where $f(x^*) = 0$. This
773 function has the following form:

$$774 f(x) = \sum_{i=1}^n x_i^2 \quad \text{Eq. 21}$$

775 4.22 Styblinski-Tang Function

776 The Styblinski-Tang function has steep valleys and multiple local minima and hence is recognized
777 for its utility in testing optimization algorithms [62]. This function is multimodal, with each
778 variable contributing quadratically and quartically to the output. This function can be suitable for
779 evaluating the efficiency of algorithms in high-dimensional spaces and their capability to scale
780 with increasing dimensionality (which makes it appropriate for practical engineering problems

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

781 involving material design and circuit optimization with multiple variables required to be
782 simultaneously optimized). The global minimum for this function is at $x_i = -2.903534x$ (for all i)
783 where $f(x) = -39.16599n$ (where n is the number of dimensions). This function has the following
784 form:

$$785 \quad f(x) = \frac{1}{2} \sum_{i=1}^n (x_i^4 - 16x_i^2 + x_i^5) \quad \text{Eq. 22}$$

786 4.23 Three-hump Camel Function

787 This function is named for its shape, resembling three camel humps and is designed as a simple
788 and effective benchmark for testing optimization algorithms [63]. This function can be used to
789 evaluate an algorithm's capability to escape local minima and find the global minimum. The
790 Three-hump Camel function has a global minimum at $(x,y)=(0,0)$ where $f(x,y)=0$. This function
791 has the following form:

$$792 \quad f(x, y) = 2x^2 - 1.05x^4 + \frac{x^6}{6} + xy + y^2 \quad \text{Eq. 23}$$

793 4.24 Whitley's Function

794 Whitley's function is known for its complex landscape with a high number of local minima [51].
795 This function is tests algorithms for their ability to distinguish subtle gradient changes and avoid
796 premature convergence. This function can be used for complex, real-world problems such as
797 landscape exploration and molecular configuration. This function has the following form:

$$798 \quad f(x) = \sum_{i=1}^n \sum_{j=1}^n \left(\frac{100(x_i^2 - x_j)^2 + (1 - x_j)^2}{4000} - \cos(200(x_i^2 - x_j)^2 + (1 - x_j)^2) + 1 \right) \quad \text{Eq. 24}$$

799 Table 2 includes the name of each function, its typical domain range, primary characteristics,
800 known challenges, and the dimensionality for which the function is typically evaluated. Figure 1
801 compares these functions visually.

802 Table 2 Holistic comparison of the examined functions.

Function Name	Domain Range	Characteristics	Challenges	Typical Dimensionality	Minima/ Minimum
Ackley	(-5, 5)	Nearly flat outer region, large hole	Global minimum difficult to find due to flatness	Multiple	0
Alpine	(-10, 10)	Multimodal, peaks and valleys	Peaks make locating global minima challenging	Multiple	0

811

Two sets of experiments were conducted to evaluate the performance of the FFO algorithm. In the first, we examine the performance of the FFO algorithm and the other listed algorithms against the aforementioned benchmark functions in 2D settings. Then, we examine the algorithmic performance against the scalable functions at higher dimensions (20D and 50D). In all cases, the experiments entitled a comparison of algorithmic performance in terms of best fitness and fitness history

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

812 achieved, time taken to execute the analysis per algorithm, trajectory analysis, and a combined
813 combination of metrics. All of these items are discussed herein in detail.

814 The best fitness is defined as the most favorable value of the objective function obtained in an
815 analysis by an algorithm across all of its iterations or agents. This metric is traced progressively,
816 with the algorithm updating this metric whenever an improved solution is found. Then, the
817 execution time is defined as the total time from the start of its execution until it terminates.
818 Trajectory refers to the sequence of points that document the position of agents (or the best agent)
819 in the search space. This distance is calculated by summing up the Euclidean distances between
820 consecutive points in the trajectory. Further, four additional categories were used to evaluate the
821 selected algorithms. These include documenting the performance of algorithms in terms of
822 identifying the functions that took the longest (and shortest) time to solve and those that achieved
823 the most (and least) accuracy.

824 To facilitate a leaner comparison, the execution time and distance explored metrics were combined
825 into a new metric named the Distance per Unit Time metric. This metric directly measures the
826 average distance covered per unit of time, which is directly interpretable as:

$$827 \text{Distance per Unit Time metric} = \frac{\text{Total distance}}{\text{Execution time}}$$

828 This measures how much distance is covered on average per second. Therefore, higher values
829 indicate more efficient exploration of the search space.

830 The conducted analysis was ran and evaluated in a Python 3.10.5 environment using an Intel(R)
831 Core(TM) i7-9700F CPU @ 3.00GHz and an installed RAM of 32.0GB. To ensure fairness, the
832 control parameters of FFO and the 13 metaheuristics employed in the performance evaluation
833 simulation were presented earlier and are found in our simulation script. In all cases, all algorithms
834 ran for 100, 1000, and 3000 iterations and with 10, 50, and 100 agents. As mentioned above, the
835 first leg of the analysis focused on all benchmarking functions at 2D, and the second leg focused
836 on scalable functions (12 out of the original 24 functions) at higher dimensions (20D and 50D).

837 *2D setting*

838 Table 3 and Fig. 2 list the overall obtained results from the analysis carried out on all algorithms
839 and functions in 2D setting. This table presents a comparative performance analysis of various
840 optimization algorithms based on metrics such as best fitness, execution time, and distance
841 metrics. Ant Colony Optimization, for instance, shows a mean best fitness of 1.22E+05 with high
842 variability (standard deviation of 9.48E+05) and ranges from -563 to 7.35 in its best fitness
843 performance. In terms of spatial efficiency, it maintains a low average distance metric (mean of
844 0.092). On the other hand, the Firefly algorithm demonstrates a broader range in execution time,
845 peaking at 1803 seconds, and exhibits a significantly wider spread in the distance metric, reaching

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

846 up to 91,600. The FFO with additional conditions³ "OFF" significantly improves best fitness and
 847 execution efficiency and large exploration capabilities to a maximum of 1.20E+08. It is quite clear
 848 that the FFO ranked well in all metrics and achieved the top ranking in terms of the Distance per
 849 Unit Time metric.

850
851

Fig. 2 Ranking of algorithms in 2D settings

³ The FFO (with additional conditions OFF) runs the FFO in a similar fashion to the other algorithms (i.e., to the same number of iterations without any additional stopping criteria). The counterpart version (with additional conditions ON) runs the FFO with all stopping criteria as described above. A true comparison between all algorithms should rely on the OFF version and hence is maintained herein.

854 Now, we gain further insights into the performance of all algorithms across different settings
855 through the illustration presented in Fig. 3. This figure shows a sample of trends collected on the
856 selected functions to show how the algorithms perform. It is quite clear that the FFO performs
857 similarly to other algorithms. For example, the first sub-figure highlights performance variations
858 of several optimization algorithms on the Ackley function at 2D, with a specific focus on the
859 number of agents employed. The FFO with additional conditions "OFF" consistently maintains
860 lower fitness values across all agent configurations compared to most algorithms, suggesting
861 higher efficiency. This is in contrast to algorithms like Bat algorithm and Ant Colony Optimization,
862 which show a marked increase in average best fitness. The FFO with additional conditions "OFF"
863 outperforms the latter at higher agent counts, which indicates better scalability with increasing
864 agents. Similar observations can also be made in terms of the algorithmic performance with the
865 number of iterations – especially in the case of the Egg Holder function, which shows superior
866 performance for the FFO algorithm.

Fig. 3 Sample of trends across different experimental settings

870
871

872 Here, we analyze and rank the performance of optimization algorithms across various settings,
873 specifically focusing on the dimensions, maximum iterations, and the number of agents involved
874 in terms of identifying those that took the longest (and shortest) time to solve, and that achieved
875 the most (and least) accuracy. This process was conducted at each unique setting. First, we rank
876 the algorithms by returning the top three entries of the specified metric and setting. Then, we
877 aggregate these frequencies both locally (for each setting) and globally (across all settings) to
878 provide a comprehensive view of which algorithms consistently perform well or underperform
879 across varied configurations.

880 We report that the Firefly algorithm appears predominantly in the longest to solve category with a
881 total of 27 out of 27 occurrences. This suggests that the Firefly algorithm, despite its potential
882 advantages in exploring complex landscapes, tends to have longer execution times compared to
883 other algorithms in the study. This could be due to its inherent characteristics, such as the
884 attractiveness parameter and light intensity, which might cause slower convergence, especially in
885 scenarios involving complicated objective functions. The FFO (additional conditions ON)
886 algorithm consistently appears as the fastest solver, also with 27 instances. This algorithm was
887 followed by the Tabu Search. The success in this category indicates the algorithmic potential for
888 applications requiring quick solutions where computational resources can be limited.

889 In the most accurate category, the Cuckoo Search leads with 9 occurrences, followed by the FFO
890 (additional conditions OFF) with 5 occurrences and various other algorithms. The notable
891 performance of Cuckoo Search could be attributed to its unique search capabilities, leveraging
892 Lévy flights for global search combined with a probabilistic switch to local search. On the other

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

893 hand, the Ant Colony Optimization is predominantly featured in the least accurate category with
894 25 instances. This might indicate ACO's challenges in maintaining high accuracy across the
895 settings tested, potentially due to its reliance on pheromone trails, which might lead to premature
896 convergence or difficulty in escaping local optima in certain types of problems.

897 Other sets of comparisons between selected algorithms can be seen in Fig. 4. For example, Fig. 4a
898 compares the average history fitness across all functions and for all algorithms. This figure shows
899 that the FFO (additional conditions OFF) demonstrates a rapid convergence initially compared to
900 others like the Bat and Grey Wolf Optimizer, which exhibit more gradual improvements. Figure 4b
901 compares the best fitness achieved in FFO, Tabu Search, the Bat, and the Grey Wolf Optimizer
902 algorithms. In this figure, FFO (additional conditions OFF) excels in deeply multi-modal landscapes
903 like the Ackley and Griewank functions. This suggests that FFO (additional conditions OFF) is
904 particularly adept at managing and escaping local optima in complex search spaces. The graph
905 also shows minimal variance in performance across different configurations (agent counts and
906 iteration limits), indicating the robustness and effectiveness of this algorithm.

907 Figure 4c shows the performance of all algorithms in tackling continuous and non-continuous
908 functions to provide a clear comparison of how each algorithm handles different types of function
909 landscapes. Here, the FFO (additional conditions OFF) shows comparable performance in both
910 categories, underscoring its versatility. More specifically, in continuous functions, it ranks among
911 the top performers, closely competing with algorithms like Particle Swarm Optimization and
912 Genetic Algorithm. The FFO (additional conditions OFF) also shows similar performance in non-
913 continuous functions. These figures further show the comparative performance and consistency of
914 the newly proposed FFO algorithm against those well established methods.

924

To complement the above analysis, the Friedman and Wilcoxon non-parametric statistical tests for ranking the above algorithm were carried out [64,65]. These statistical methods can evaluate and compare the performance of optimization algorithms across multiple functions. The Friedman test

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

925 ranks algorithms based on their mean performance across all tested functions, where a lower rank
 926 indicates superior performance (i.e., achieving better, usually lower, fitness values). Each function
 927 is treated equally, and the ranks are averaged to provide an overall ranking for each algorithm. The
 928 test then checks if the observed rankings are statistically significant.

929 On the other hand, the Wilcoxon test focuses on pairwise comparisons between algorithms. This
 930 test calculates the signed rank of the differences in performance between each pair to assess
 931 whether one algorithm consistently outperforms the other. While both tests aim to highlight the
 932 best-performing algorithms, they approach the evaluation from slightly different perspectives—
 933 Friedman emphasizes overall ranking across all scenarios, while Wilcoxon emphasizes
 934 consistency in pairwise dominance. Figure 5 shows the outcome of these tests. As one can see, the
 935 FFO ranks 4 and 5 in these tests, respectively. PSO, GWO, and FPO rank in the top three spots.

936

937

Fig. 5 Friedman and Wilcoxon non-parametric statistical tests for 2D

938 *20D and 50D setting*

939 Similar to the previous analysis and discussion, Table 4 and Fig. 6 list the overall obtained results
 940 from the analysis carried out on all algorithms and functions in higher dimensions of 20D and 50D.
 941 Thus, only scalable functions were used in this examination. These functions include Ackley,
 942 Eggholder, Easom, Expanded Shaffer's F6, Expanded Zakharov, Griewank, Gldstien-Price,
 943 Rosenbrock, Schaffer N.02, Schwefel, Sphere, and Whitely.

944 In this comparative analysis, the FFO (additional conditions OFF) demonstrates a creditable mean
 945 best fitness of $2.88E+03$, which, while not the lowest in our dataset, offers a viable trade-off
 946 between fitness achievement and computational resources when compared to algorithms like the
 947 Simulated Annealing, which has a lower mean best fitness of $5.17E-02$ but at a significantly

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

948 reduced complexity. In terms of execution time, the FFO (additional conditions OFF) records a
 949 mean of $9.35E+02$ seconds, positioning it as a middle-range performer. It is notably faster than
 950 high-accuracy contenders such as the Firefly algorithm and the Biogeography-Based Optimization,
 951 which clocks in at mean times of $2.93E+02$ seconds and $1.06E+01$ seconds, respectively, reflecting
 952 a more efficient performance considering the relatively lower fitness figures.

953 On a more positive note, the FFO (additional conditions OFF) has signifncat exploration capability,
 954 as measured by the Total Distance metric, where it posts a mean of $1.58E+07$. This is significantly
 955 higher than that of the Particle Swarm Optimization and Grey Wolf Optimizer, which stand at
 956 $2.98E+05$ and $3.10E+04$, respectively. Moreover, the Distance per Unit Time for the FFO (with
 957 conditions OFF) is large and stands at $2.95E+06$, shadowing those of Cuckoo Search and Harmony
 958 Search, which report $3.41E+01$ and $2.85E+03$, respectively. This metric highlights the FFO's
 959 efficiency in covering large distances in the search space per unit of time, reinforcing its utility in
 960 expansive and complex problem spaces where speed and breadth of exploration are paramount. It
 961 is quite clear that the FFO ranked well in all metrics (see Fig. 6).

962

Please cite this paper as:

Naser M.Z., Naser, A. (2025). The firefighter algorithm for optimization problems. *Neural Computing and Applications*. <https://doi.org/10.1007/s00521-025-11074-z>.

974 We revisit the ranking performance of the optimization algorithms across the longest (and
975 shortest) time to solve and that achieved the most (and least) accuracy. Similar to the case of 2D,
976 the Firefly algorithm leads this category with an appearance frequency of 75, indicating it often
977 requires the most time to solve the selected benchmark functions. On the other hand, the Ant Colony
978 Optimization appears far less frequently with a count of 6, suggesting a quicker resolution time but
979 possibly at the expense of other performance metrics like accuracy or search depth. Then, the
980 Simulated Annealing dominates the fastest to solve category and hence demonstrates its ability to
981 swiftly find solutions. In terms of accuracy, Cuckoo Search stands out with 22 appearances,
982 followed by the FFO (additional conditions OFF) and Particle Swarm Optimization, each scoring 13
983 occurrences. The Ant Colony Optimization leads as the least accurate with 29 appearances,
984 followed by the Bat Algorithm at 19, suggesting these algorithms might prioritize exploration or
985 speed over precision.

986 Figure 8 paints a series of comparisons between selected algorithms. Figure 8a compares the
987 average history fitness across all functions and algorithms. This graph shows the average fitness
988 history across iterations for various optimization algorithms. The FFO (additional conditions OFF)
989 starts with a rapid convergence compared to other algorithms, which is particularly noticeable
990 against the backdrop of more gradual improvements shown by the Genetic Algorithm and
991 Simulated Annealing. The FFO (additional conditions OFF) demonstrates a stabilization around 200
992 iterations, where its fitness value flatlines. This early convergence suggests that, on average, this
993 algorithm is efficient in quickly finding a promising area of the search space.

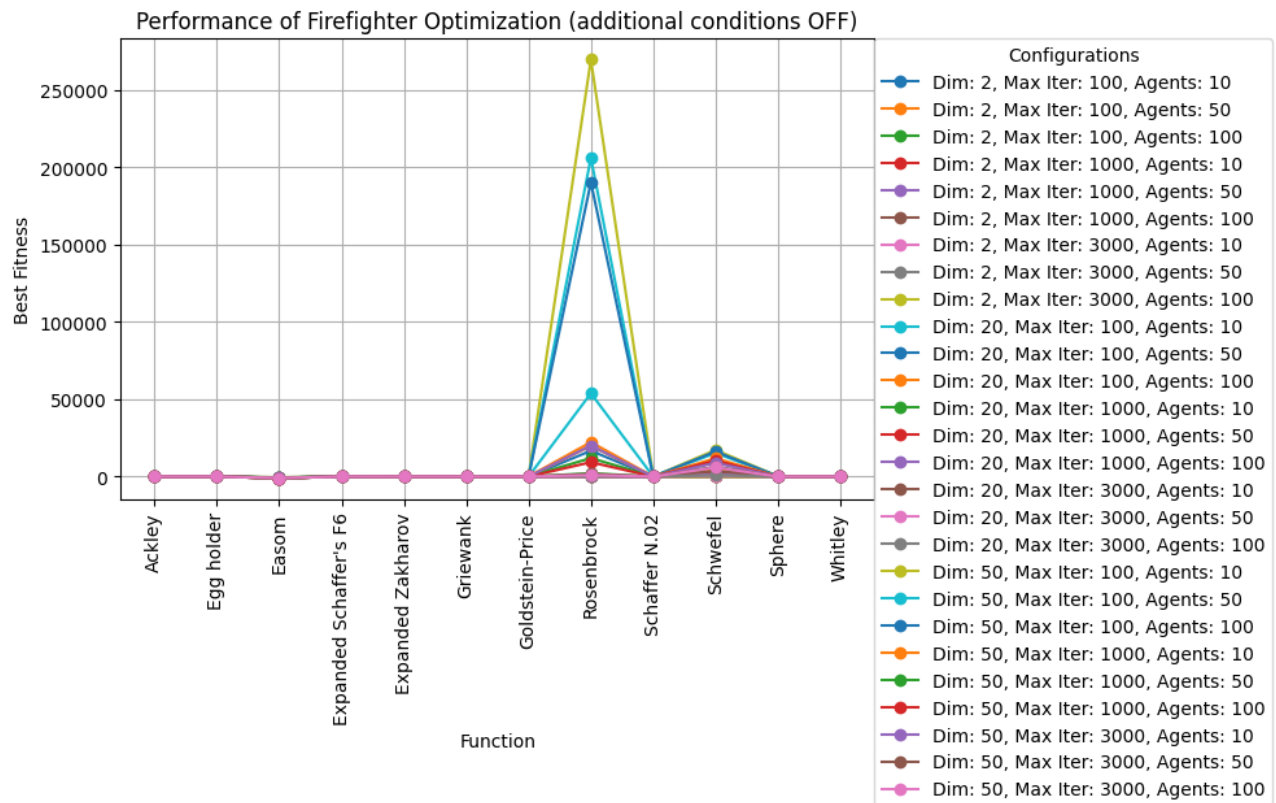

994 While Fig. 8b compares the best fitness achieved in FFO, Tabu Search, the Bat, and the Grey Wolf
995 Optimizer algorithms. In Fig. 8b, the performance of FFO (additional conditions OFF) is plotted
996 across various scalable functions under different settings, showing stable performance for all
997 functions, except the Rosenbrock, and especially under conditions of higher iterations and larger
998 agent numbers. These spikes indicate that FFO (additional conditions OFF) can excel in complex,
999 multimodal landscapes but show variable performance dependent on the function's characteristics
1000 and the search space complexity. Comparing this performance to other algorithms, such as Tabu
1001 Search, Bat, and Grey Wolf Optimizer, across the same benchmark functions shows generally stable
1002 performance as well, with some exceptions where fitness spikes, similar to the behavior seen in
1003 FFO. Figure 8c shows the performance of all algorithms in tackling continuous and non-continuous
1004 scalable benchmarking functions. The FFO (additional conditions OFF) shows competitive
1005 performance in all function types. These figures reinforce the performance of the newly proposed
1006 FFO algorithm against notable algorithms.

Additional testing on functions from the CEC benchmarks (at 2D, 20D and 50D settings)

1024

The IEEE Congress on Evolutionary Computation (IEEE CEC) is an annual conference that focuses on the latest developments and research in evolutionary computation. As part of this conference, benchmark functions are commonly used to evaluate the performance of optimization algorithms. These benchmark functions, often called CEC functions, are specifically designed to present various challenges to optimization methods, such as multimodality, non-separability, and

1025

1026

1027

1028

Please cite this paper as:

1035

1036 The outcome of this analysis is listed in Table 6. This table shows that both FFO and PSW ranked
1037 first in terms of overall ranking among all metrics. In addition, Fig. 10 shows that the best version
1038 of FFO ranked between 3 and 6 for the Friedman and Wilcoxon non-parametric statistical tests,
1039 respectively. Overall, PSO, GA, and CS achieved the best rankings in this experiment.

1052 *Real engineering problems*

1053 The CEC benchmark suit also contains several constraints and real engineering problems
1054 commonly used in the benchmarking analysis. As such, five additional engineering problems were
1055 examined herein. Table 6 lists these problems and their characteristics. It should be noted that the
1056 mathematical derivation for these problems is not included herein for brevity, yet it can be easily
1057 accessible from the original source of CEC 2020, as well as in [67]. The Friedman and Wilcoxon
1058 non-parametric statistical tests were carried out for each problem individually. Each problem was
1059 run with the following settings: Agents [25, 50, 100] and iterations [25, 100, 100]. Table 7 and
1060 Fig. 11 show the outcome of this analysis as well as a comparative history run for the three-bar
1061 truss design problem. Overall, it can be seen that the proposed algorithm has a decent performance,
1062 ranking within the top 5 spots in each problem (and first on the distance covered), with its best
1063 performance recorded on the three-bar truss design problem. This analysis also shows the need to
1064 improve further and tune FFO to allow it to enhance its performance on real engineering problems.

1065 Table 6 CEC 2020 engineering problems.

No.	Functions	No. of constraints	Objective/Remark
10	Process flow sheeting problem	3	Minimize the flow sheeting process
17	Tension/Compression spring design	4	Optimize the weight of a spring
18	Pressure vessel design	4	Optimize the welding cost, material, and forming
19	Three-bar truss design problem	3	Minimize the weight of the bar structures

1079 *Future research needs*

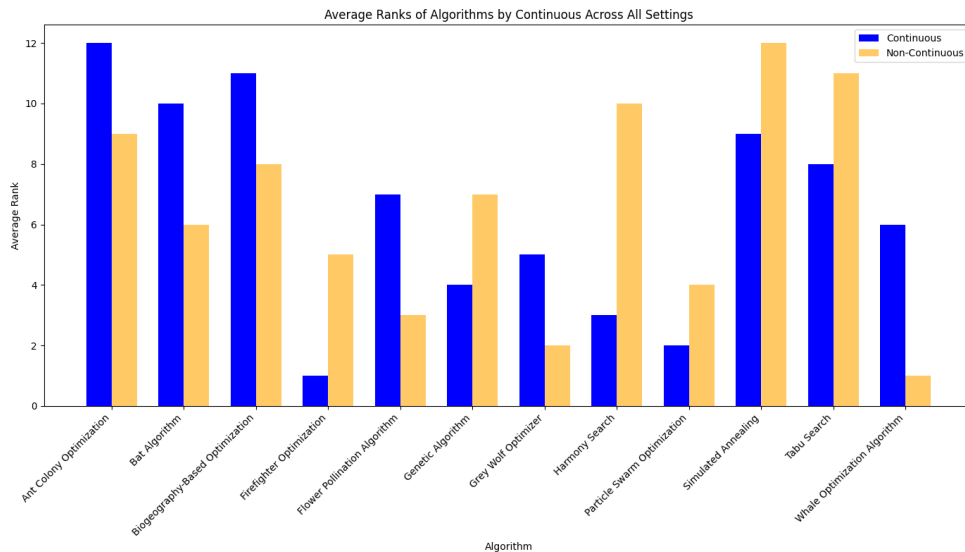

1080 In order to further examine the performance of the proposed algorithm, we present a new set of
1081 results (see Fig. 12). In this analysis, we focus on function attributes like continuity, separability,
1082 multimodality, differentiability, and performance in continuous function optimization are
1083 demonstrated. The plots assess performance based on the average of metrics and visually display
1084 how each algorithm performs across these attributes under the specific settings.

1085 This figure shows results produced by filtering for specific settings (Iterations=1000, Agents=100)
1086 and merging these results with predefined function attributes. These plots reveal distinct
1087 performance characteristics that generally show more modest peaks across the attributes,
1088 suggesting that some algorithms perform better in handling specific functions (i.e., Separable
1089 functions). For example, the FFO algorithm ranks first and fifth in continuous functions, first and
1090 fourth in differentiable and non-differentiable, second and sixth on multimodal and non-
1091 multimodal functions, fifth in scalable and non-scalable functions, and eighth and fifth on
1092 separable and non-separable functions.

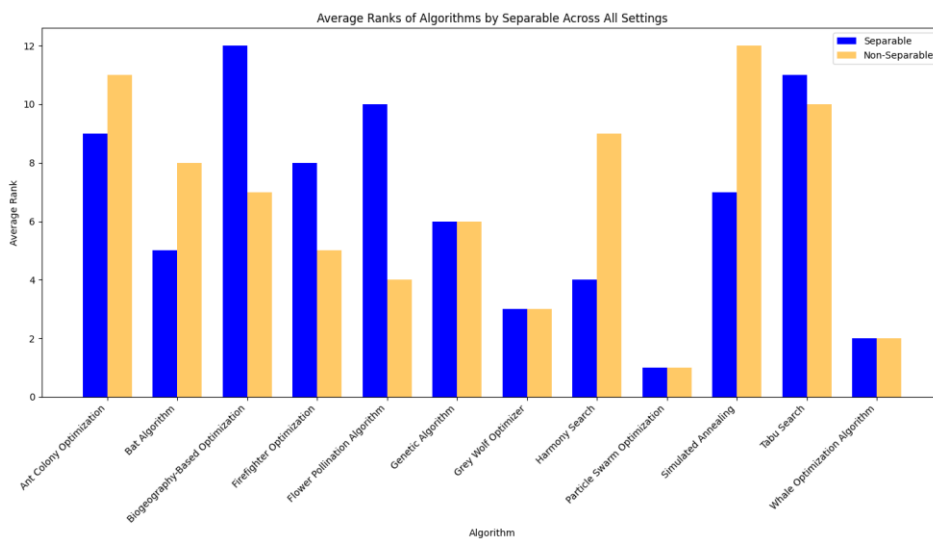

1093 These insights, together with those gained from the testing on real engineering problems, can also
1094 provide technical improvement areas for FFO (as well as the selected algorithms). For example,
1095 FFO could focus on enhancing its performance in non-separable and multimodal landscapes,
1096 perhaps by integrating more adaptive search strategies or improving its handling of function
1097 differentiability through better derivative estimation or step size adjustment mechanisms.
1098 Additionally, efforts to boost scalability could be crucial, especially for handling higher-
1099 dimensional optimization problems more effectively. In addition, there is a need to further examine
1100 the proposed algorithms against some of the recently developed algorithms (namely, SASS,
1101 COLSHADE, sCMAGES). At the moment, the performance of FFO can indeed be improved to
1102 match it with the aim of further enhancing it against the aforementioned leading algorithms. In
1103 addition, the authors hope that future editions from FFO include multi- and many-objective
1104 optimization capabilities.

6.0 Conclusions

1112 The Firefighter optimization (FFO) algorithm offers a metaheuristic approach for optimization. This
1113 algorithm was examined against 13 commonly used optimization algorithms and 38 functions
1114 (including benchmark functions, CEC 2020 standard functions, and real engineering problems).
1115 Our results demonstrate that in 2D analysis, FFO ranks in the top 3 slots in terms of the best fitness
1116 and space covered and ranks first in the Distance per Unit Time metric. Similarly, the performance
1117 of the FFO algorithm also ranks third in higher dimensions (20D and 50D) and maintains a top 5
1118 performance across various metrics. Our analysis also indicates a few possible means to improve
1119 the performance of FFO, primarily on scalable/non-scalable functions and separable/non-separable
1120 functions, as well as on performing on real optimization problems.

Data Availability

1122 Some or all data, models, or code that support the findings of this study are available from the
1123 corresponding author upon reasonable request.

1124 Firefighter optimization (FFO) can be accessed from [to be added].

Conflict of Interest

1126 The authors declare no conflict of interest.
